

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

Chemotaxis of sperms of *Equisetum*.—LIDFORSS,³⁶ to avoid anticipation by SHIBATA, has made a preliminary announcement of his discovery that the spermatozoids of *Equisetum* are markedly chemotactic toward solutions of malic acid especially, and also to maleic acid and its salts. Only indifference is shown to solutions of fumaric acid or of its salts. The threshold concentration of malic acid he finds to be about M/10000. Aerotaxis, which had been previously observed in the case of *Marchantia* spermatozoids, could not be demonstrated.—RAYMOND H. POND.

***Welwitschia*.**—*Tumboa mirabilis* is so little known that any fresh observations are welcome. PEARSON³⁷ succeeded in securing material showing the development of microsporangia, microspores, megasporangia and megaspores. Observations were made upon the habit, habitat, and climatic conditions. It is probable that the plant is partially, if not wholly, insect-pollinated, and that the processes of fertilization and maturation of the seed take place more rapidly than in other gymnosperms.—CHARLES J. CHAMBERLAIN.

The cycadean integument.—This is discussed in a recent paper by Miss STOPES,³⁸ who takes this occasion to compare the structures of the cycad ovule with those of the fossil *Lagenostoma*. The single integument of the living cycads is regarded as a double structure representing two integuments of some ancestral form. The plane of fusion of the two integuments has been between the inner and outer layers of the stony coat, or between the stone and the outer flesh.—CHARLES J. CHAMBERLAIN.

A rust-resistant cantaloup.—BLINN³⁹ finds that the Pollock strain of cantaloups is resistant to the rust or blight which is a common and serious disease in the Rocky Ford district of Colorado. This resistance he found was transmitted through seed selected from resistant plants, and hence seed selection becomes a very practical method of controlling this destructive disease wherever it may occur. The disease is due to the fungus *Macrosporium cucumerinum* E. & E.—E. MEAD WILCOX.
